What Is Thermochemistry? Definition and Scope

Thermochemistry is a branch of chemistry that deals with the study of heat changes that occur during chemical reactions and physical processes. It involves understanding how energy is transferred in the form of heat during reactions, phase changes, and other transformations.

Core Concepts in Thermochemistry

- Enthalpy (ΔH):** The heat content of a system at constant pressure.
- Endothermic and Exothermic Reactions:** Reactions that absorb or release heat, respectively.
- Heat Capacity:** The amount of heat required to change the temperature of a substance.
- Specific Heat:** Heat capacity per unit mass.
- Calorimetry:** The experimental measurement of heat transfer.

Importance of Assessment Answers in Thermochemistry

Assessment answers are vital for several reasons:

- Self-Assessment:** They help students evaluate their understanding of thermochemical concepts.

Common Types of Thermochemistry Assessment Questions

Understanding the typical questions asked in assessments can prepare students better. Here are prevalent question types:

- 1. Conceptual Questions** Define key terms such as enthalpy, calorimetry, or specific heat. Explain the difference between endothermic and exothermic reactions. Describe the significance of Hess's Law in thermochemistry.
- 2. Calculation-Based Questions** Calculate the heat absorbed or released during a reaction. Determine the enthalpy change using calorimetry data. Use Hess's Law to find the enthalpy change of a reaction when given multiple steps.
- 3. Graphical Analysis** Interpret temperature vs. heat graphs. Analyze energy diagrams for chemical reactions. Identify activation energy and transition states.
- 4. Application and Real-World Scenarios** Calculate energy needs for heating or cooling processes. Assess calorimetric data for chemical processes. Apply thermochemical principles to industrial or biological systems.

Sample Assessment Questions and Answers

Providing examples with detailed solutions can greatly aid in understanding. Here are some typical questions with their answers:

Question 1: What is the enthalpy change of the reaction if 50.0 g of water (specific heat = $4.18 \text{ J/g}^\circ\text{C}$) is heated from 25°C to 75°C ?

Answer: Calculate the heat absorbed (q):

$$q = m \times c \times \Delta T$$

$$q = 50.0 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C} \times (75^\circ\text{C} - 25^\circ\text{C})$$

$$q = 50.0 \times 4.18 \times 50$$

$$q = 50.0 \times 209$$

$$q = 10,450 \text{ J}$$

Since this is a heating process with no chemical

reaction involved, the enthalpy change (ΔH) for the process is 10,450 J (or 10.45 kJ).

Question 2: Using Hess's Law, determine the enthalpy change for the reaction:

$$\text{C} + 2\text{H}_2 \rightarrow \text{CH}_4$$
Given:

$$\text{C} + \text{O}_2 \rightarrow \text{CO}_2 \quad \Delta H = -393.5 \text{ kJ}$$

$$2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O} \quad \Delta H = -571.6 \text{ kJ}$$

$$\text{CH}_4 + 2\text{O}_2 \rightarrow \text{CO}_2 + 2\text{H}_2\text{O} \quad \Delta H = -890.3 \text{ kJ}$$
Answer: Rearrange the reactions to find the target: The target reaction can be derived as:

$$\text{C} + 2\text{H}_2 \rightarrow \text{CH}_4$$
Use Hess's Law:

$$\Delta H_{\text{target}} = \Delta H_1 + \Delta H_2 + \text{(appropriate adjustments)}$$
But since the given reactions are:

$$\text{C} + \text{O}_2 \rightarrow \text{CO}_2 \quad (\Delta H = -393.5 \text{ kJ})$$

$$2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O} \quad (\Delta H = -571.6 \text{ kJ})$$

$$\text{CH}_4 + 2\text{O}_2 \rightarrow \text{CO}_2 + 2\text{H}_2\text{O} \quad (\Delta H = -890.3 \text{ kJ})$$
Reverse reaction 3:

$$\text{CO}_2 + 2\text{H}_2\text{O} \rightarrow \text{CH}_4 + 2\text{O}_2 \quad \Delta H = +890.3 \text{ kJ}$$
Add reactions 1, 2, and the reversed 3:

$$\text{C} + \text{O}_2 \rightarrow \text{CO}_2$$

$$2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$$

$$\text{CO}_2 + 2\text{H}_2\text{O} \rightarrow \text{CH}_4 + 2\text{O}_2$$
Sum:

$$\text{C} + \text{O}_2 + 2\text{H}_2 + \text{O}_2 + \text{CO}_2 + 2\text{H}_2\text{O} \rightarrow \text{CO}_2 + 2\text{H}_2\text{O} + \text{CH}_4 + 2\text{O}_2$$
Cancel common terms:

$$\text{CO}_2$$
 on both sides cancels.

$$2\text{H}_2\text{O}$$
 cancels.
Remaining:

$$\text{C} + 2\text{H}_2 \rightarrow \text{CH}_4$$
Sum the enthalpy changes:

$$\Delta H = -393.5 + (-571.6) + 890.3 = -393.5 - 571.6 + 890.3 = -75.8 \text{ kJ}$$
Therefore, ΔH for the formation of methane from carbon and hydrogen is approximately -75.8 kJ.

In-Depth Review of Key Concepts with Answers

1. Calculating Heat Transfer in Calorimetry

Question: A 50.0 g sample of water is heated from 25°C to 75°C. How much heat energy is absorbed? (Specific heat capacity of water = 4.18 J/g°C)

Answer: Using the formula: $q = mc\Delta T$ where: $m = 50.0\text{ g}$, $c = 4.18\text{ J/g}^\circ\text{C}$, $\Delta T = 75^\circ\text{C} - 25^\circ\text{C} = 50^\circ\text{C}$

Calculation: $q = 50.0\text{ g} \times 4.18\text{ J/g}^\circ\text{C} \times 50^\circ\text{C}$

$q = 50.0 \times 4.18 \times 50 = 10,450\text{ J}$

Result: The water absorbs 10,450 Joules of heat energy.

2. Applying Hess's Law

Question: Given the following reactions:

$$\text{C} + \text{O}_2 \rightarrow \text{CO}_2 \quad (\Delta H = -393.5\text{ kJ})$$

$$\text{CO} + \frac{1}{2} \text{O}_2 \rightarrow \text{CO}_2 \quad (\Delta H = -283\text{ kJ})$$

Find ΔH for the reaction:

$$\text{C} + \frac{1}{2} \text{O}_2 \rightarrow \text{CO}$$

Answer: Using Hess's Law, arrange the reactions to cancel out common terms:

From the second reaction:

$$\text{CO} + \frac{1}{2} \text{O}_2 \rightarrow \text{CO}_2$$

Reversing it:

$$\text{CO}_2 \rightarrow \text{CO} + \frac{1}{2} \text{O}_2 \quad (\Delta H = +283\text{ kJ})$$

Now, add this to the first reaction:

$$\text{C} + \text{O}_2 \rightarrow \text{CO}_2 \quad (\Delta H = -393.5\text{ kJ})$$

$$\text{CO}_2 \rightarrow \text{CO} + \frac{1}{2} \text{O}_2 \quad (\Delta H = +283\text{ kJ})$$

Sum: $\text{C} + \text{O}_2 + \text{CO}_2 \rightarrow \text{CO}_2 + \text{CO} + \frac{1}{2} \text{O}_2$

Simplify: $\text{C} + \frac{1}{2} \text{O}_2 \rightarrow \text{CO}$

Total

enthalpy change: $(-393.5 \text{ kJ} + 283 \text{ kJ} = -110.5 \text{ kJ})$ Result: $\boxed{\Delta H = -110.5 \text{ kJ}}$ for the formation of CO from C and O_2 .

3. Bond Enthalpy Calculations Question: Calculate the approximate enthalpy change for the reaction: $\text{CH}_4 + 2 \text{O}_2 \rightarrow \text{CO}_2 + 2 \text{H}_2\text{O}$, using bond enthalpies provided:

Bond	Enthalpy (kJ/mol)
C-H	412
C=O	799
O=O	498

Answer: Step 1: Break all bonds in reactants: 4 C-H bonds: $(4 \times 412 = 1648 \text{ kJ})$ 2 O=O bonds: $(2 \times 498 = 996 \text{ kJ})$ Total energy to break bonds: $(1648 + 996 = 2644 \text{ kJ})$ Step 2: Form bonds in products: 2 C=O bonds in CO_2 : $(2 \times 799 = 1598 \text{ kJ})$ 4 O-H bonds in 2 H_2O molecules: $(4 \times 463 = 1852 \text{ kJ})$ (assuming O-H bond enthalpy is 463 kJ/mol) Total energy released: $(1598 + 1852 = 3450 \text{ kJ})$ Step 3: Calculate ΔH : $\Delta H \approx \text{Energy to break} - \text{Energy to form} = 2644 - 3450 = -805 \text{ kJ}$ Result: Approximate enthalpy change for the reaction is -805 kJ (exothermic).

Overview of Thermochemistry

Thermochemistry is a branch of thermodynamics focused on the study of heat changes during chemical reactions and physical processes. It involves understanding how energy is absorbed or released, quantifying these changes, and applying thermodynamic principles to analyze systems.

Key Concepts in Thermochemistry

Endothermic and Exothermic Reactions: Reactions that absorb heat (endothermic) versus those that release heat (exothermic).

Enthalpy (ΔH): A measure of the total heat content of a system at constant pressure.

Heat Capacity and Specific Heat: The amount of heat needed to change the temperature of a substance.

Hess's Law: The total enthalpy change for a reaction is the same regardless of the pathway taken.

Calorimetry: The experimental technique used to measure heat changes in chemical reactions.

Common Review Questions and Their Answers

Studying thermochemistry involves tackling a variety of questions that test conceptual understanding and calculation skills. Here are some typical review questions along with detailed answers.

1. What is the difference between heat and temperature?

Answer: Heat refers to the transfer of thermal energy between systems due to a temperature difference and is measured in joules (J) or calories. Temperature, on the other hand, is a measure of the average kinetic energy of particles in a substance, expressed in degrees Celsius, Kelvin, or Fahrenheit. While heat involves energy transfer, temperature is a state function indicating thermal intensity.

2. How do you calculate the heat absorbed or released in a physical or chemical process?

Answer: The heat (q) can be calculated using the formula: $q = mc\Delta T$ where: m = mass of the substance, c = specific heat capacity, ΔT = change in temperature (final - initial). For chemical reactions, enthalpy changes (ΔH) are often used, especially at constant pressure, and can be determined through calorimetry or Hess's Law.

3. What is Hess's Law, and how is it useful in

thermochemistry? Answer: Hess's Law states that the total enthalpy change for a reaction is the same, regardless of the number of steps or pathway taken, provided the initial and final states are the same. It is useful because it allows us to calculate enthalpy changes for reactions that are difficult to measure directly by combining known reactions with their enthalpy changes.

4. How do you determine the enthalpy change of a reaction using bond energies? Answer: The enthalpy change can be estimated with bond energies as follows:
$$\Delta H = \sum \text{Bond Energies of bonds broken} - \sum \text{Bond Energies of bonds formed}$$
 This involves summing the energy required to break bonds in the reactants and subtracting the energy released when new bonds form in the products.

5. What is calorimetry, and how is it used to measure heat transfer? Answer: Calorimetry is an experimental technique used to measure the heat involved in chemical or physical processes. A calorimeter isolates the system from the surroundings and measures temperature changes caused by the process. The amount of heat transferred is calculated using the calorimeter's heat capacity and the observed temperature change.
